

A $G_\sigma * (K * H) = (G_\sigma * K) * H$

residual $\|\Delta\|_2 / \|\cdot\|_2 = 2.7 \times 10^{-16}$

Blurring the output equals convolving with a pre-blurred stamp: the blur folds into the weights once.

B $G_\sigma \circ \rho \neq \rho \circ G_\sigma$

A blur slides back through a convolution, but not past a ReLU.

C σ fixed in layer pixels

The same blur covers a larger share of a smaller map: $\pi\sigma^2/(HW)$ grows $\times 16$.
